# INTRODUCTION I

- Injection of CO<sub>2</sub> in deep saline aquifers is a procedure used for reducing the amount of greenhouse gases in the atmosphere.
- This work studies CO<sub>2</sub> injection into the Utsira formation at the Sleipner gas field. The Utsira sandstone is a highly permeable porous medium with several mudstone layers which act as barriers to the vertical upward flow of CO<sub>2</sub>.
- First, pressure and CO<sub>2</sub> saturation maps are generated using a multiphase fluid flow simulator. Then, time lapse seismic is used to determine the spatio-temporal distribution of CO<sub>2</sub> applying a viscoelastic wave propagation simulator.

INTERNATIONAL EXPOSITION AND 87TH  
ANNUAL MEETING

## INTRODUCTION II

- The petrophysical model of the Utsira formation assumes fractal porosity and clay content, taking into account the variation of properties with pore pressure and saturation.
- Since CO<sub>2</sub> injection changes the porosity and permeability flow parameters, a sensitivity analysis is performed to determine the time step at which such parameters need to be updated.
- The wave propagation simulator takes into account mesoscopic loss effects due to the presence of CO<sub>2</sub> within the Utsira sand.
- The frequency dependent Lamè parameters at the macroscale are determined from the pressure and saturation maps computed by the flow simulator.

# METHODOLOGY

- Use a Black-Oil multiphase fluid flow numerical simulator to model CO<sub>2</sub> injection into the Utsira formation at the Sleipner field.
- Include variations in flow parameters due to changes in pressure and saturation
- Use a wave propagation simulator including mesoscopic loss effects to monitor the spatio-temporal distribution of CO<sub>2</sub> in the formation.

The basic concepts and ideas used in this presentation can be found in the book

***Numerical Simulation in Applied Geophysics***

# BLACK OIL MODEL OF BRINE-CO2 FLOW I

Mass conservation equation ( $g = \text{CO}_2$ ,  $w = \text{brine}$ )

$$-\nabla \cdot \left( \frac{1}{B_g} \bar{v}_g + \frac{R_s}{B_w} \bar{v}_w \right) + q_g = \frac{\partial \left[ \phi \left( \frac{S_g}{B_g} + \frac{R_s S_w}{B_w} \right) \right]}{\partial t}$$

$$-\nabla \cdot \left( \frac{1}{B_w} \bar{v}_w \right) + q_w = \frac{\partial \left[ \phi \frac{S_w}{B_w} \right]}{\partial t}$$

$\phi$ : porosity     $S_i$ : phase  $i$  saturation     $p_i$ : phase  $i$  pressure     $q_i$ : flow rate per unit volume

$i = g, w$

$R_s$ : gas solubility in water     $B_g$ : gas formation volume factor

$B_w$ : water formation volume factor

# BLACK OIL MODEL OF BRINE-CO2 FLOW II

## Darcy's Empirical Law ( $g = \text{CO}_2$ , $w = \text{brine}$ )

$$\bar{v}_g = -\bar{K} \frac{k_{rg}}{\eta_g} (\nabla p_g - \rho_g g \nabla z)$$

$$\bar{v}_w = -\bar{K} \frac{k_{rw}}{\eta_w} (\nabla p_w - \rho_w g \nabla z)$$

$$S_w + S_g = 1 \quad p_g - p_w = P_C(S_g)$$

$\bar{v}_i$  = Darcy velocity       $\bar{K}$ : absolute permeability tensor       $\eta_i$ : phase  $i$  viscosity

$k_{ri}(S_i)$ : phase  $i$  relative permeability       $P_C(S_g)$ : gas-water capillary pressure

## NUMERICAL MODEL OF WATER-GAS FLOW II

- The numerical solution is obtained employing the public domain software **BOAST**.
- **BOAST** solves the flow differential equations using **IMPES** (IMplicit Pressure Explicit Saturation), a finite difference technique.
- The basic idea of **IMPES** is to solve:
  - ✓ A pressure equation: obtained combining the flow equations for both phases.
  - ✓ A saturation equation: flow equation for the brine phase.

# IMPES TECHNIQUE

- The **IMPES** system is linearized evaluating the pressure and saturation dependent coefficients at the previous time step.
- The pressure equation is solved implicitly, applying a Block Successive Over Relaxation method (BSOR).
- The saturation equation is solved explicitly, therefore stability restrictions are considered to select the flow time step.

# MESOSCOPIC LOSS AND WAVE PROPAGATION SIMULATIONS I

- A dominant P-wave attenuation mechanism in reservoir rocks at seismic frequencies is due to wave-induced fluid flow (WIFF, mesoscopic loss).
- Fast P and S-waves travelling through mesoscopic-scale heterogeneities (larger than the pore size but smaller than the wavelength), induce fluid flow and slow (diffusion) Biot waves by mode conversion.
- The wave propagation simulator used at the macroscale allows to represent the mesoscopic loss mechanism

## MESOSCOPIC LOSS AND WAVE PROPAGATION SIMULATIONS II

- In zones where CO<sub>2</sub> is present, the complex and frequency dependent P-wave modulus at the macroscale

$$E(\omega) = \lambda(\omega) + 2\mu(\omega)$$

is determined using White's theory for patchy saturation (White et al., Physics of Solid Earth, 1975)

$\lambda(\omega)$  ,  $\mu(\omega)$  : Lamè coefficients,  $\omega$  : angular frequency.

- Shear wave attenuation is taken into account using another relaxation mechanism, related to the P-wave White mechanism.

## MESOSCOPIC LOSS AND WAVE PROPAGATION SIMULATIONS III

- In zones where only brine is the saturating fluid, the complex bulk and shear moduli as function of frequency were determined using a Zener model.

These complex moduli define an equivalent viscoelastic model at the macroscale that takes into account dispersion and attenuation effects occurring at the mesoscale

# SEISMIC MODELING. A VISCOELASTIC MODEL FOR WAVE PROPAGATION

Equation of motion in a 2D isotropic viscoelastic domain  $\Omega$ :

$$\omega^2 \rho \mathbf{u} + \nabla \cdot \boldsymbol{\sigma}(\mathbf{u}) = f(x, \omega), \quad \Omega$$

$$-\boldsymbol{\sigma}(\mathbf{u})\mathbf{v} = i \omega \mathbf{D} \mathbf{u}, \quad \partial\Omega$$

$f(x, \omega)$  = external source       $\mathbf{D}$ : positive definite matrix

The solution of the viscoelastic wave equation was computed at a selected number of frequencies in the range of interest using an iterative Finite Element (FE) domain decomposition procedure.

# THE PARAMETERS OF THE FLUID FLOW AND SEISMIC MODELS I

The formation is a uniform shaly sand with clay content  $C = 6\%$  and initial fractal porosity.

The pressure dependence of properties of the flow parameters is defined by the relation between porosity  $\phi(t)$  and pore pressure  $p(t) = S_w p_w(t) + S_g p_g(t)$  (Carcione et al., J. Appl. Physics, 2003),

$$\frac{1 - \phi_c}{K_s} (p(t) - p_H) = \phi_0 - \phi(t) + \phi_c \ln \left( \frac{\phi(t)}{\phi_0} \right)$$

$\phi_c$ : critical porosity       $K_s$ : bulk modulus of solid grains

$p_H$  = hydrostatic pressure       $\phi_0$ : initial porosity

INTERNATIONAL EXPOSITION AND 87TH  
ANNUAL MEETING  
HOUSTON • TEXAS  
24-29 SEPTEMBER 2017

## THE PARAMETERS OF THE FLUID FLOW AND SEISMIC MODELS II

- The relationship among horizontal permeability  $k_x$ ,  $\phi$  and  $C$  is (Carcione et al., 2003),

$$\frac{1}{k_x(t)} = \frac{45(1 - \phi(t))^2}{\phi(t)^3} \left( \frac{(1 - C)^2}{R_q^2} + \frac{C^2}{R_c^2} \right)$$

$R_q$ : radius of sand grains     $R_c$ : radius of clay grains

- As permeability is anisotropic, the following relationship between horizontal  $k_x$  and vertical permeability  $k_z$  is assumed:

$$\frac{k_x(t)}{k_z(t)} = \frac{1 - (1 - 0.3a) \sin(\pi S_w)}{a(1 - 0.5 \sin(\pi S_w))}$$

$a$ : permeability anisotropy parameter

## THE PARAMETERS OF THE FLUID FLOW AND SEISMIC MODELS III

The Krief equation (Krief et al., The Log Analyst, 1990) is used to determine the bulk and shear moduli of the dry matrix,  $K_m$ ,  $\mu_m$  :

$$K_m(t) = K_s (1 - \phi(t))^{A/(1-\phi(t))} \quad \mu_m(t) = \mu_s (1 - \phi(t))^{A/(1-\phi(t))}$$

Using the moduli  $K_s$ ,  $K_m$ ,  $\mu_m$ , the porosity  $\phi$  and permeabilities  $k_x$ ,  $k_z$ , as well as the fluids bulk moduli and viscosities, in zones where CO2 is present the complex and frequency dependent plane wave modulus  $E(\omega)$  was determined using White's theory for patchy saturation (White et al., 1975)

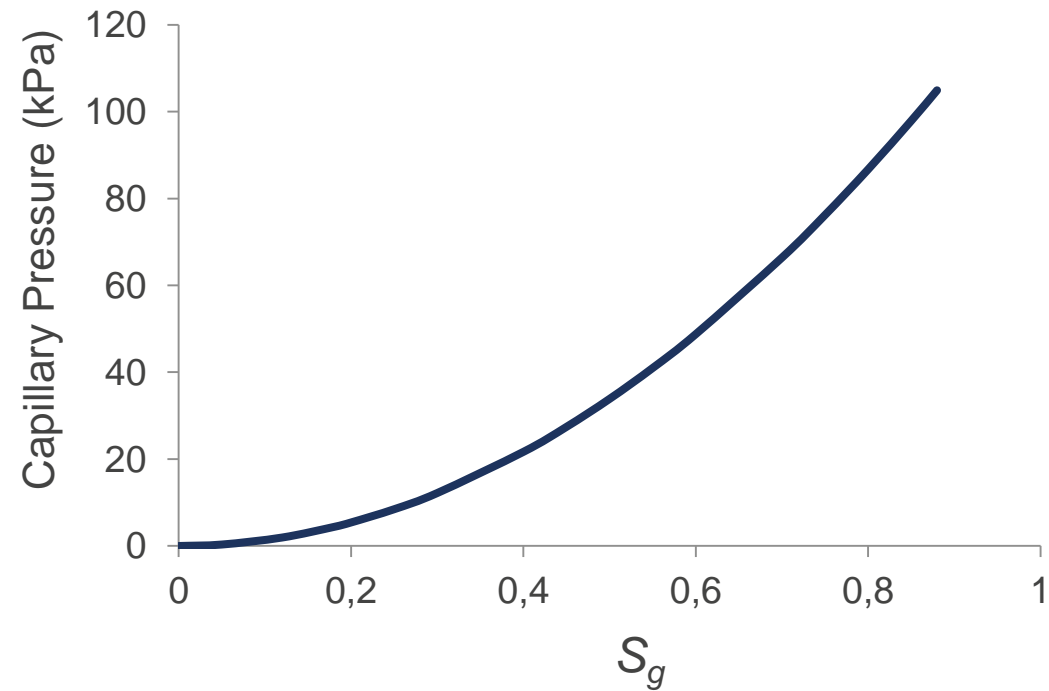

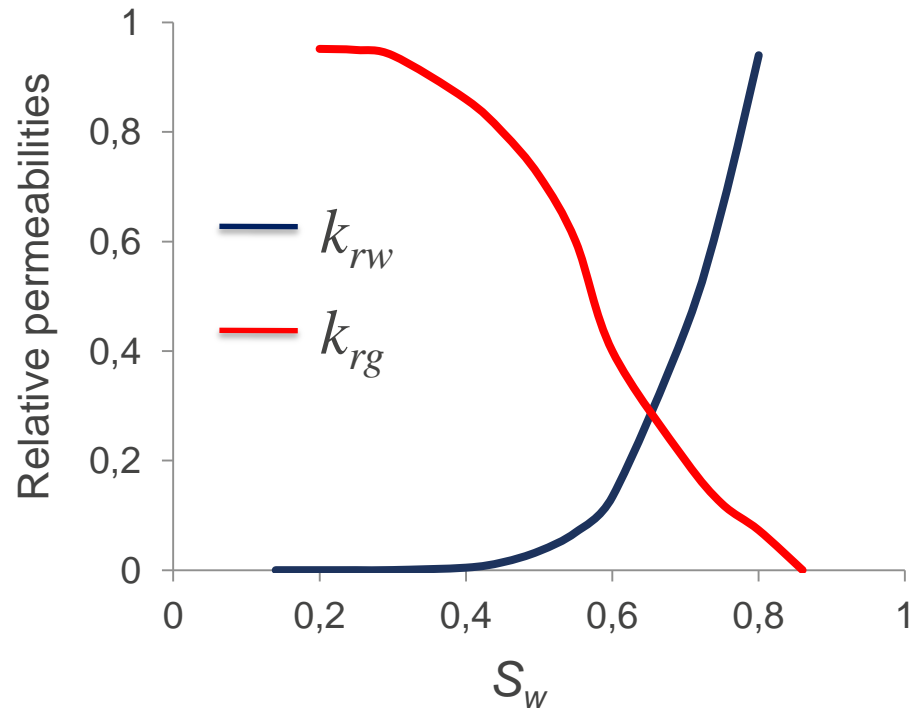

# NUMERICAL EXAMPLES I

- Consider a 2D section of the Utsira formation with 1.2 km in the x-direction and 0.4 km in the z-direction (top at 0.77 km and bottom at 1.17 km b.s.l.)
- Within the formation, there are several low permeability mudstone layers, but with openings giving a path for the upward migration of CO<sub>2</sub>.
- CO<sub>2</sub> is injected at a constant flow rate of one million tons per year. The injection point is located at the bottom of the formation:  $x = 0.6$  km,  $z = 1.082$  km (Arts et al., First Break, 2008).
- The flow simulator uses a uniform mesh of 300 cells in the x-direction and 400 cells in the z-direction.

# NUMERICAL EXAMPLES II – The flow functions

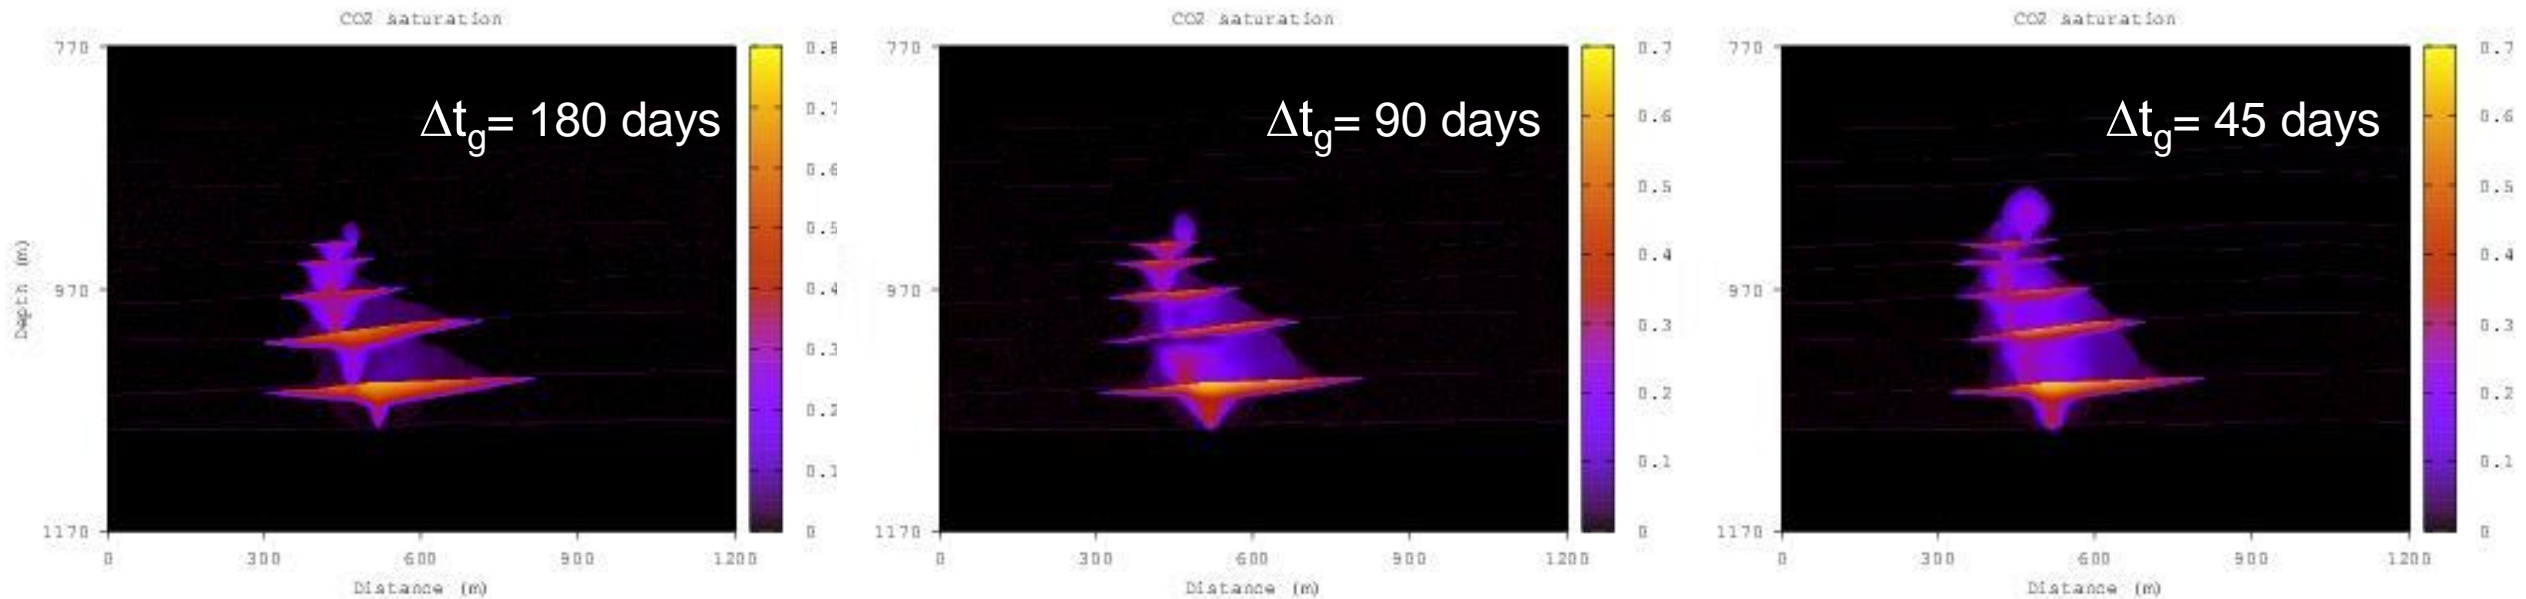

## NUMERICAL EXAMPLES III

- During the CO<sub>2</sub> injection simulation, significant changes in  $(k, \phi)$  occur at times much larger than the flow time step  $\Delta t_f$ . Thus we need two levels of temporal discretizations:
- 1) A flow time step  $\Delta t_f = 0.08$  day satisfying the CFL stability condition, to solve the flow equations.
  - 2) A formation time step  $\Delta t_g$  at which the flow parameters  $(k, \phi)$  depending on pressure and saturation are updated.

Thus numerical experiments are performed to determine the largest  $\Delta t_g$  at which the results of the flow simulations (pressure and saturation) remain essentially unchanged.

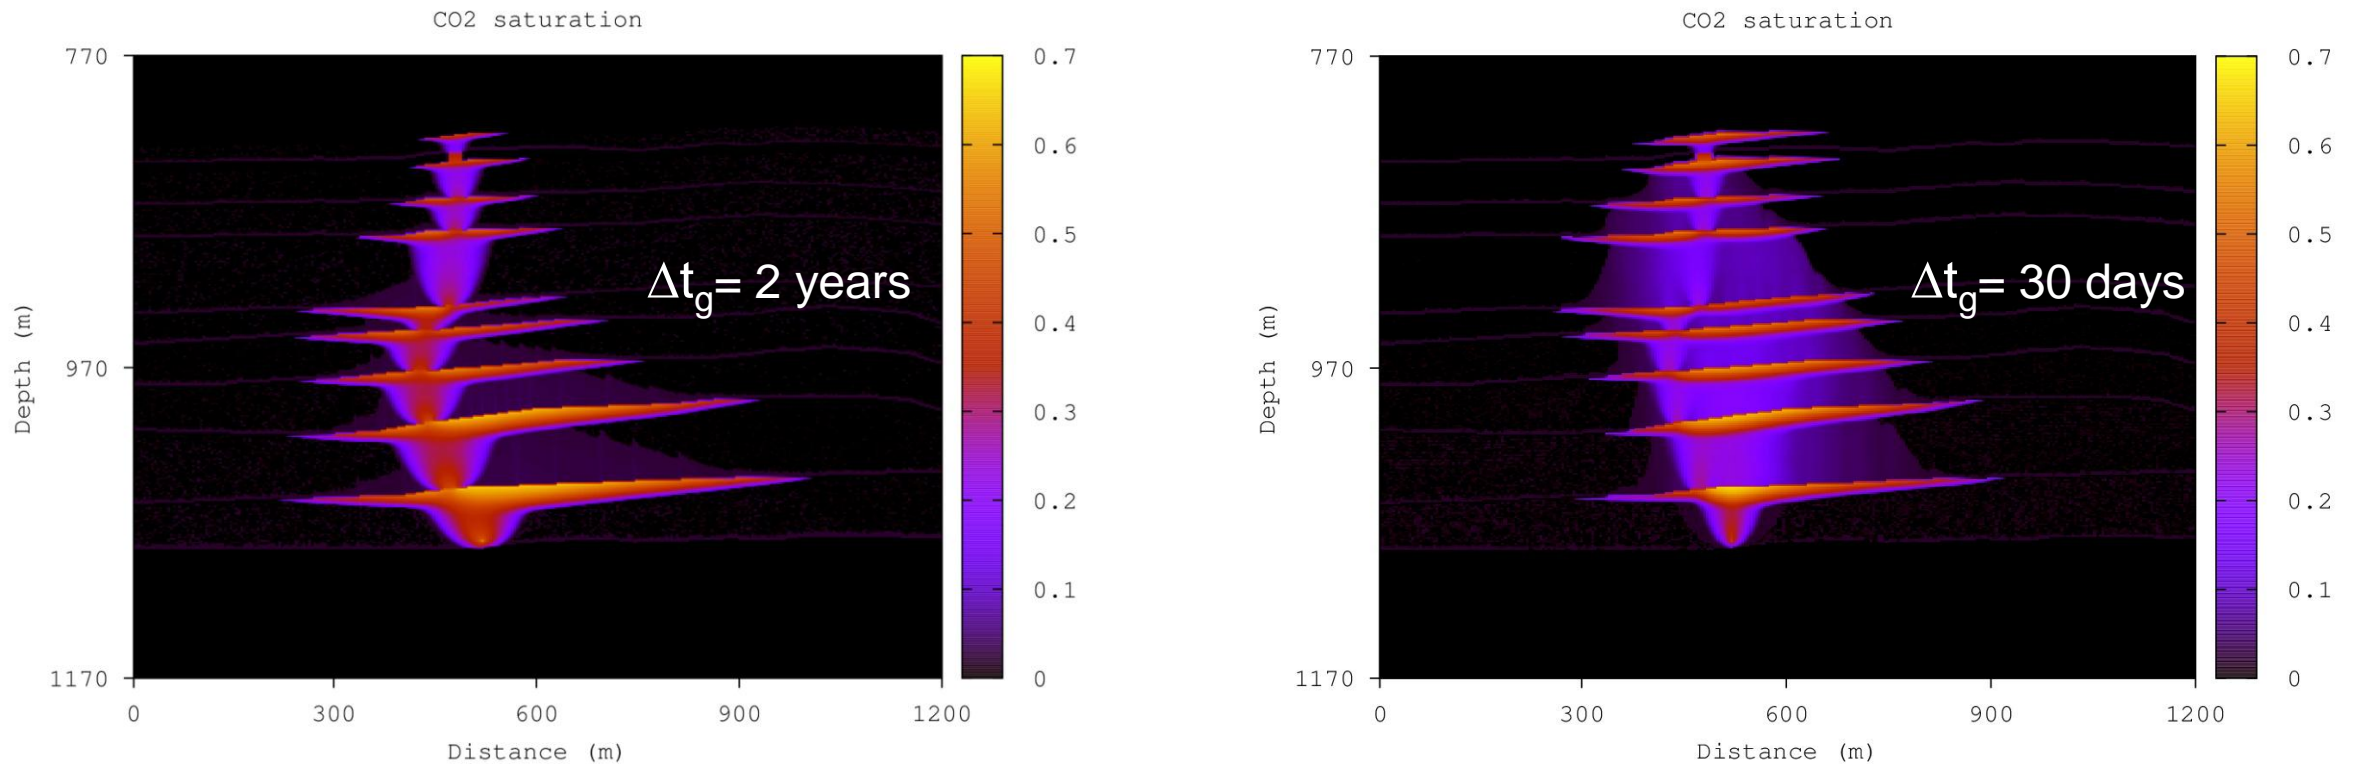

# Sensitivity analysis for different $\Delta t_g$ and 1 year of injection

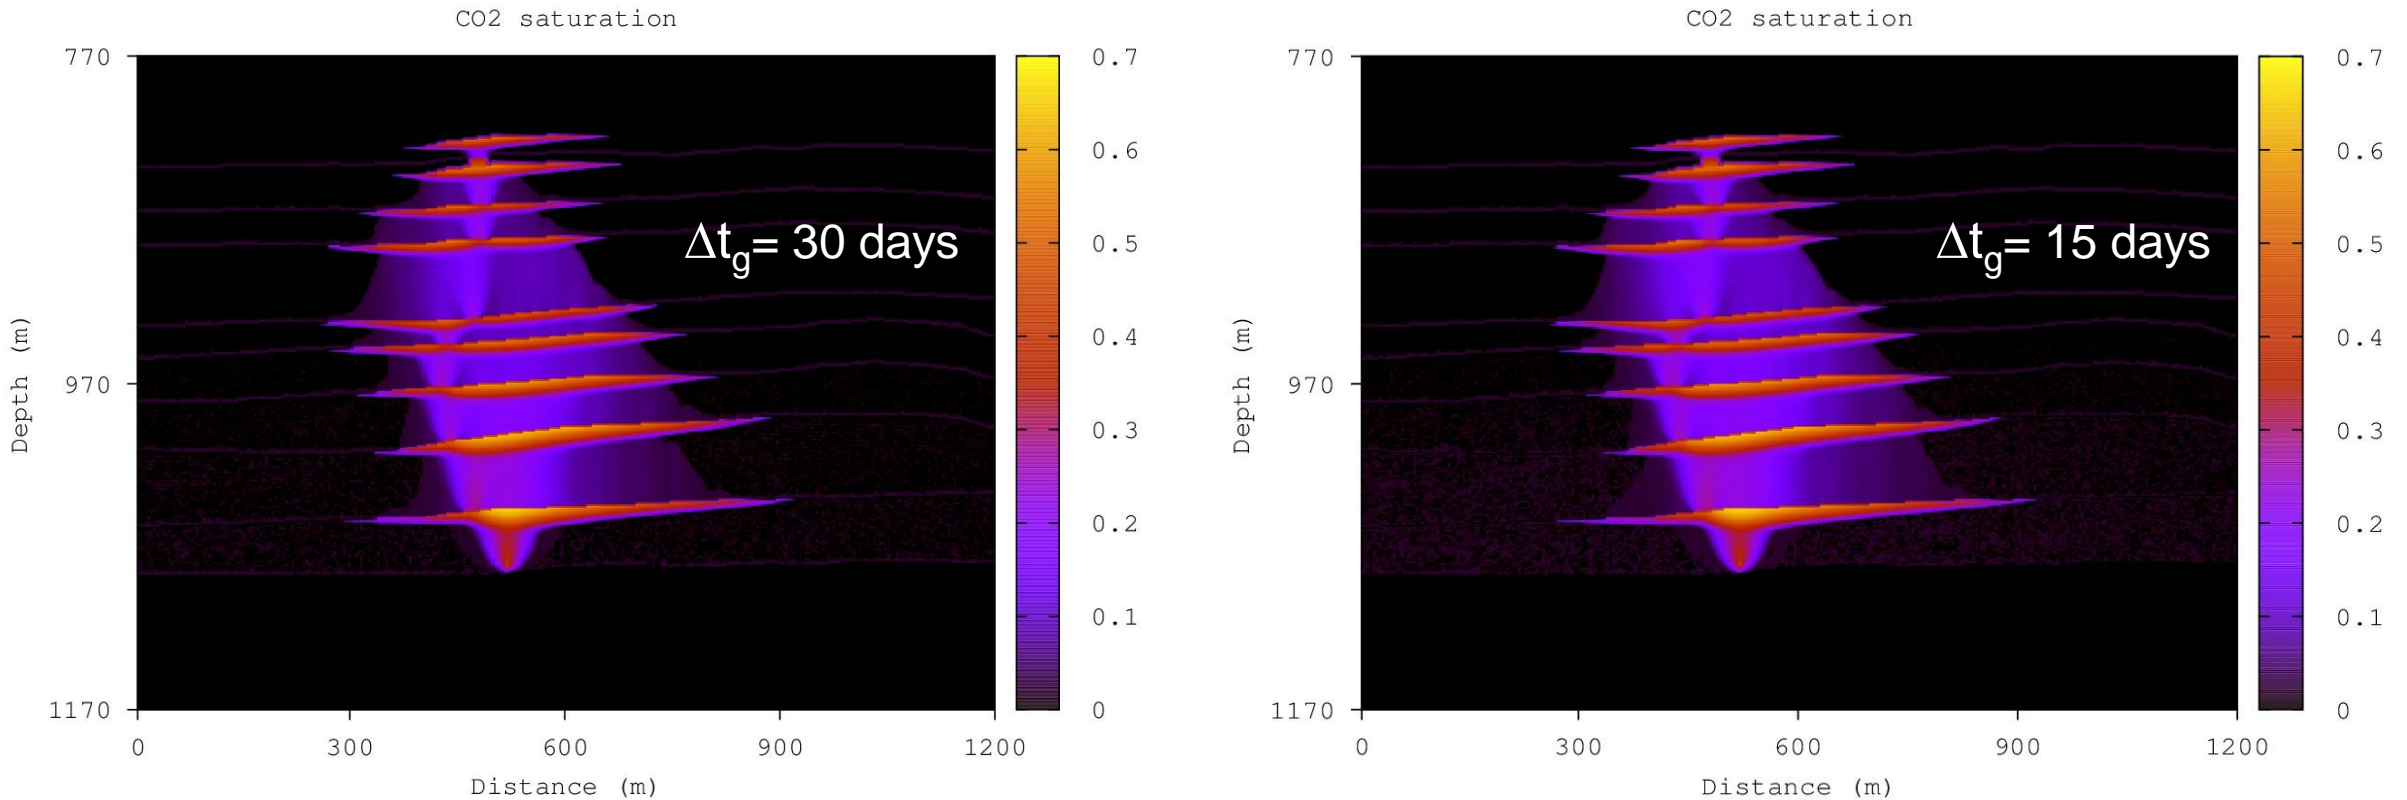

Because  $k_z$  is saturation dependent, the CO2 plume is seen to move upwards faster when the petrophysical properties are updated more frequently, i.e., as  $\Delta t_g$  is reduced

# Saturation maps after two years of CO2 injection

The left figure, obtained without updating flow parameters, shows very well defined chimneys and accumulations below the mudstone layers. The right figure, computed updating every 30 days, displays a less defined chimney, thinner accumulations and more extended CO2 zones between mudstone layers.

# Saturation maps after two years of CO2 injection

These two very similar figures show that it is enough to use a formation time step  $\Delta t_g$  of 30 days to update the parameters ( $k$ ,  $\phi$ ) in the flow simulator.

The quadratic relative error between the two maps is about 0.22%

# Time Lapse Seismic applied for monitoring CO2 injection I

- We apply the wave propagation simulator to analyze the effect of updating the petrophysical and seismic properties in the synthetic seismograms.
- The simulator includes mesoscopic loss effects associated with the presence of CO2 as injection proceeds, as described above.

# CO2 saturation and synthetic seismogram after 1 year of injection without updating parameters

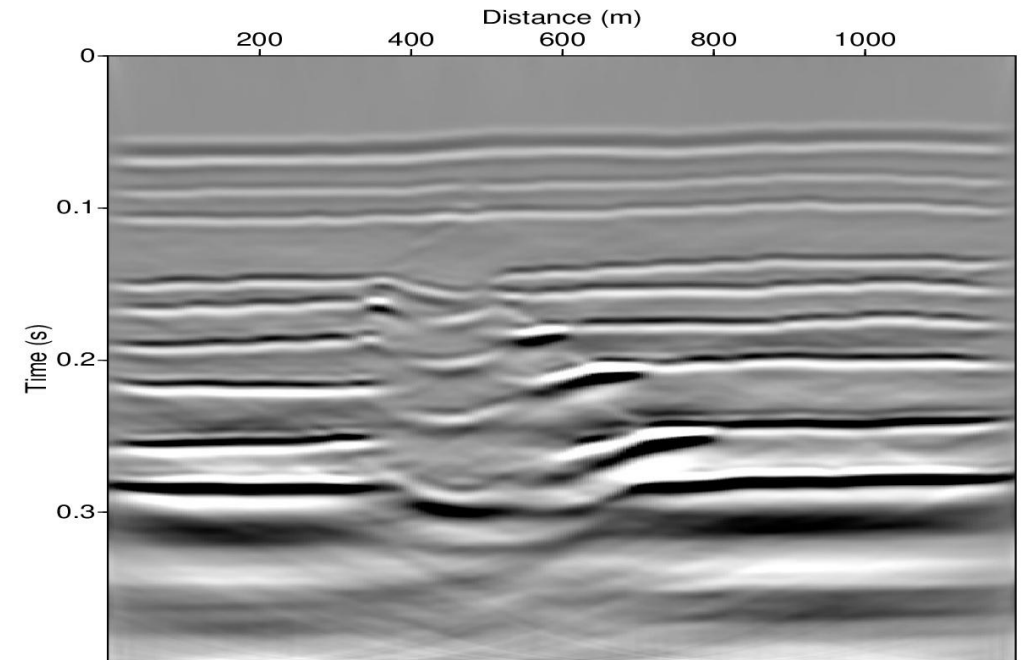

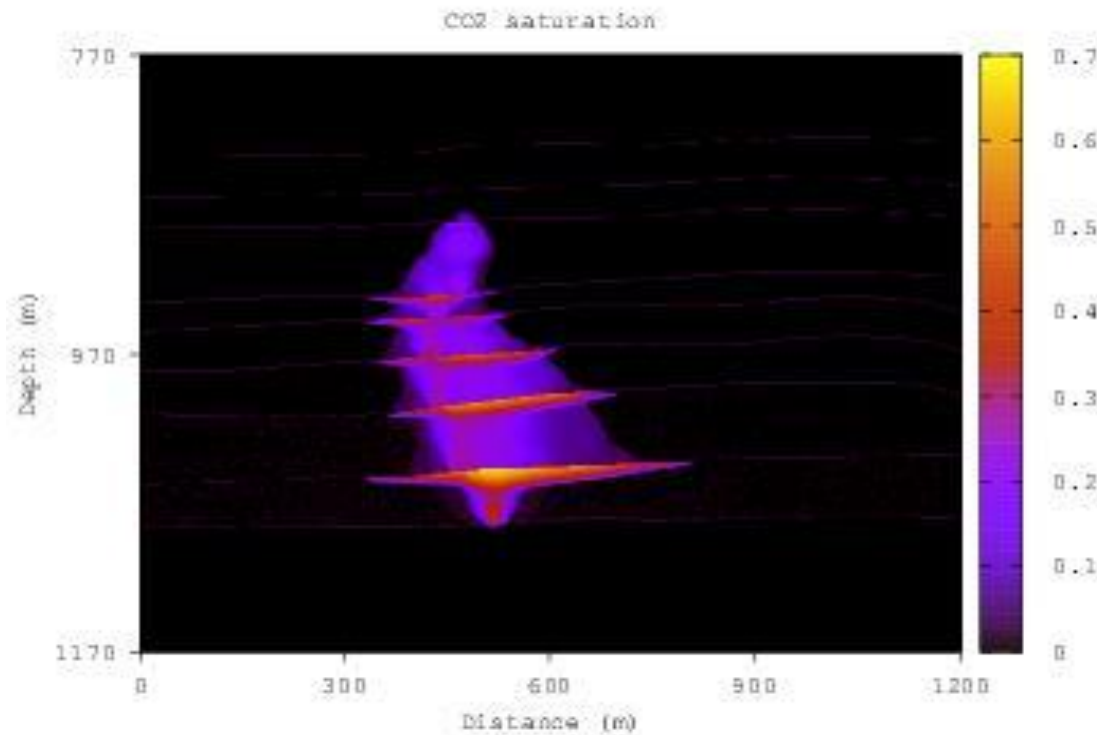

The CO2 plume induces the pushdown effect

ANNUAL MEETING  
HOUSTON • TEXAS  
24-29 SEPTEMBER 2017

# CONCLUSIONS I

- We presented a methodology to determine the flow and formation time steps to apply time lapse seismics for monitoring CO2 injection in saline aquifers.
- The methodology, when applied to the Utsira formation, yielded a suitable formation time step of 30 days.
- Using this formation time step to update the simulation parameters allowed to obtain accurate seismic images of the spatial distribution of CO2 after injection.

# CONCLUSIONS

- Furthermore, a precise definition of the zone where the pushdown effect occurs is obtained.
- The delay observed in the pushdown region, of about 50 ms, is in good agreement with that measured in real data (Chadwick et al., Proc. 6th Petroleum Geology Conference, 2005).
